

## 177. BIFRENĀRIĀ? longicōrnīs.

*B. longicornis* ; pseudobulbis elongatis tetragonis, foliis oblongo-lanceolatis subplicatis nitidis, racemo laxo multifloro, sepalis lateralibus ovatis acutis basi connatis in calcar longum clavatum productis, petalis ovatis acutis, labello longè unguiculato spathulato apice trilobo laciniis rotundatis medio pubescente disco elevato calloso, polliniis sphæricis sessilibus glandulis duabus discretis.

If this plant is really to be referred to *Bifrenaria*, it will be necessary to modify the character of that genus very considerably; for the lateral sepals are extended into a long slender clavate spur, and there are two glands as well as two caudiculæ to the pollen-masses. Its relationship to *B. aurantiaca* is however such as to make me unwilling to separate it at present. The flowers are orange spotted with brown, and in a raceme very like that of the species just mentioned. Messrs. Loddiges imported it from Demerara.
