

39. TRIGONIDIUM, *Lindl.*

Lip "jointed with the shortly produced base of the column, channelled-3-lobed:" perigonal divisions 3 exterior connate at the base, 2 interior smaller, free. "Column naked: pollinaria 4, incumbent, sessile on a semilunar gland, 2 posterior smaller."—Scape or peduncle 1-2-flowered, *distantly sheathed*; leaves *leathery*.

145. **T. monophyllum**, *Gr. (n. sp.)*. Leaf single, lanceolate-linear, obliquely emarginate at the bluntish summit, exceeded by the 2-1-flowered peduncle; perigonal divisions exterior obovate-oblong, mucronulate-bluntish, interior shorter, blunt, as long as the lip.—Of this plant there are two specimens in Herb. Hook., named "*Trigonidium*" in the handwriting of Dr. Lindley: the flowers are well preserved, but could not be analysed without destroying them. The species seems to approach *T. obtusum*, Lindl. (Bot. Reg. t. 1923), but the flowering stem is 1-leaved above its slender base, devoid of aerial tubers, the leaf is much narrower, 4" long, 4'''-5''' broad; exterior perigone spreading, divisions 9''' long, united at the base.—HAB. Jamaica!, *Bancr.*
